

Back-Face Detection

(x,y,z) is behind the polygon if
 $Ax+By+Cz < 0$

or

A polygon is a backface if

$$V_{\text{view}} \cdot N > 0$$

if V_{view} is parallel to z_v axis:

if $C < 0$ then backface

if $C = 0$ then polygon cannot
be seen

Depth-Buffer Method (z-Buffer)

Object space method

Compares depths of the surfaces and uses the color of the closest one to the view plane

Depth buffer – depth values of surfaces for (x,y)

$$0 \leq \text{depth} \leq 1$$

Frame buffer (refresh buffer) – color value for (x,y)

Depth-Buffer Method (z-Buffer)

1. $\text{depthbuffer}(x,y) = 1.0$
 $\text{framebuffer}(x,y) = \text{background color}$
2. Process each polygon one at a time
 - 2.1. For each projected (x,y) pixel position of a polygon, calculate depth z .
 - 2.2. If $z < \text{depthbuffer}(x,y)$
 - compute surface color,
 - set $\text{depthbuffer}(x,y) = z$,
 - $\text{framebuffer}(x,y) = \text{surfacecolor}(x,y)$

Depth-Buffer Method (z-Buffer)

Calculating Depth:

$$\text{At } (x,y): \quad Ax+By+Cz+D=0$$
$$z=(-Ax-By-D)/C$$

$$\text{For } (x+1, y): \quad z' = z-(A/C)$$

$$\text{For } x'=x-1/m, y'=y-1:$$
$$z' = z+(A/m+B)/C$$

A-Buffer Method

Linked list:

| | |
|-------|--------------|
| depth | surface info |
|-------|--------------|

Depth: a real number

- ≥ 0 : single surface
- < 0 : multiple surfaces

Surface info: surface data or pointer

Surface data:

- RGB intensity
- opacity
- depth
- percent of area coverage
- surface identifier
- etc.

Scan-Line Method

Image space method

For each scan-line, examine all polygon surface projections intersecting that scan line to determine which are visible. Then enter the surface color of that position in the frame buffer.

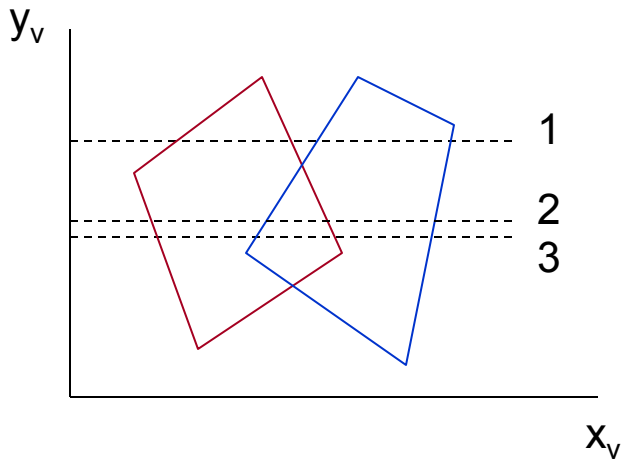

Edge table:

- coordinate endpoints of each line
- inverse slope of each line
- pointers to surface table

Surface table:

- plane coefficients (A,B,C)
- surface material properties
- pointers to edge table

Scan-Line Method

Algorithm:

1. Form an active edge list that contains only the edges that cross the current scan line, sorted in order of increasing x .
2. Define a flag for each surface to indicate whether a position along a scan line is inside or outside the surface.
3. Process pixel positions across each scan line from left to right. Locate visible positions of surfaces along the scan line.

Scan-Line Method

Divide surfaces to eliminate the overlap.

Visible Line Detection (Wireframe visibility)

If the projected edge endpoints of a line segment are both within the projected area of a surface, compare the depth of the endpoints to the surface depth at those (x,y) positions.

If both endpoints are behind the surface => **hidden edge**
If both endpoints are in front of the surface => **visible edge**

Otherwise calculate the intersections and the depth value of the intersection point.

- If for both intersection points, edge has greater depth than the surface => **part of the edge is behind the surface**
- If one edge endpoint has greater depth and the other has less depth than the surface => **edge penetrates the surface**

Then, calculate the penetration point

Depth Cueing

$f_{\text{depth}}(d)$ is multiplied by each pixel's color

$$f_{\text{depth}}(d) = (d_{\text{max}} - d) / (d_{\text{max}} - d_{\text{min}})$$

d : distance of a point from the viewing position

d_{min} : 0.0

d_{max} : 1.0
