

Chapter 8

DFA state minimization

Motivations

Problems:

1. Given a DFA M with k states, is it possible to find an equivalent DFA M' (i.e., $L(M) = L(M')$) with state number fewer than k ?
2. Given a regular language A , how to find a machine with minimum number of states ?

Ex: $A = L((a+b)^*aba(a+b)^*)$ can be accepted by the following NFA:

By applying the subset construction, we can construct a DFA M_2 with $2^4=16$ states, of which only 6 are accessible from the initial state $\{s\}$.

Inaccessible states

- A state $p \in Q$ is said to be inaccessible (or unreachable) [from the initial state] if there exists no string x in Σ^* s.t. $\Delta(s,x) = p$ (I.e., $p \notin \{q \mid \exists x \in \Sigma^*, \Delta(s,x) = q\}$.)

Theorem: Removing inaccessible states from a machine M does not affect the language it accepts.

Pf: $M = \langle Q, \Sigma, \delta, s, F \rangle$: a DFA; p : an inaccessible state

Let $M' = \langle Q \setminus \{p\}, \Sigma, \delta', s, F \setminus \{p\} \rangle$ be the DFA M with p removed.

Where $\delta' : (Q \setminus \{p\}) \times \Sigma \rightarrow Q \setminus \{p\}$ is defined by

$\delta'(q,a) = r$ if $\delta(q,a) = r$ and $q, r \in Q \setminus \{p\}$.

For M and M' it can be proved by induction on x that for all x in Σ^* , $\Delta(s,x) = \Delta'(s,x)$.

**Hence for all $x \in \Sigma^*$, $x \in L(M)$ iff $\Delta(s,x) = q \in F$
iff $\Delta'(s,x) = q \in F \setminus \{p\}$ iff $x \in L(M')$.**

Inaccessible states are redundant

- **M** : any DFA with n inaccessible states p_1, p_2, \dots, p_n .

Let M_1, M_2, \dots, M_{n+1} are DFAs s.t. DFA M_{i+1} is constructed from M_i by removing p_i from M_i . I.e.,

$$M - \text{rm}(p_1) \rightarrow M_1 - \text{rm}(p_2) \rightarrow M_2 - \dots - M_n - \text{rm}(p_n) \rightarrow M_n$$

By previous lemma: $L(M) = L(M_1) = \dots = L(M_n)$ and

M_n has no inaccessible states.

- **Conclusion:** Removing all inaccessible states simultaneously from a DFA will not affect the language it accepts.
- In fact the conclusion holds for all NFAs as well.

Pf: left as an exercise.

- **Problem:** Given a DFA (or NFA), how to find all inaccessible states ?

How to find all accessible states

- A state is said to be accessible if it is not inaccessible.

Note: the set of accessible states $A(M)$ of a NFA M is

$$\{q \mid \exists x \in \Sigma^*, q \in \Delta(S, x)\}$$

and hence can be defined by induction.

- Let A_k be the set of states accessible from initial states of M by at most k steps of transitions.

I.e., $A_k = \{q \mid \exists x \in \Sigma^* \text{ with } |x| \leq k \text{ and } q \in \Delta(S, x)\}$

- What is the relationship b/t $A(M)$ and A_k s ?
 □ sol: $A(M) = \bigcup_{k \geq 0} A_k$. Moreover $A_k \subseteq A_{k+1}$
- What is A_0 and the relationship b/t A_k and A_{k+1} ?

Formal definition: $M = \langle Q, \Sigma, \delta, S, F \rangle$: any NFA.

- Basis: Every start state $q \in S$ is accessible. ($A_0 \subseteq A(M)$)
- Induction: If q is accessible and p in $\delta(q, a)$ for some $a \in \Sigma$, then p is accessible.

$$(A_{k+1} = A_k \cup \{p \mid p \in \delta(q, a) \text{ for some } q \in A_k \text{ and } a \in \Sigma.\})$$

An algorithm to find all accessible states:

- REACH(M) { // M = $\langle Q, \Sigma, \delta, S, F \rangle$
- 1. A = S; // A = A₀
- 2. B = $\Delta(A) - A$; // B = A₁ - A₀
- 3. For k = 0 to |Q| do { // A = A_k; B = A_{k+1} - A_k
- 4. A = A \cup B; // A = A_{k+1}
 B = $\Delta(B) - A$; // B = $\Delta(B) - A = \Delta(A_{k+1} - A_k) - A_{k+1} = A_{k+2} - A_{k+1}$;
 if B = {} then break };
- 5. Return(A) }

Function $\Delta(S)$ { // = $\bigcup_{p \in S, a \in \Sigma, q \in \delta(p, a)}$

- 1. $\Delta = \{\}$;
- 2. For each q in S do
 for each a in Σ do
 $\Delta = \Delta \cup \delta(q, a)$;
- 3. Return(Δ) }

Minimization process

- **Minimization process for a DFA:**
 - 1. Remove all inaccessible states
 - 2. Merge all *equivalent* states
- **What does it mean that two states are equivalent?**
 - both *have the same observable behaviors* .i.e.,
 - there is no way to distinguish their difference.
- **Definition: we say state p and q are *distinguishable* if there exists a string $x \in \Sigma^*$ s.t. $(\Delta(p, x) \in F \Leftrightarrow \Delta(q, x) \notin F)$.**
 - If there is no such string, i.e. $\forall x \in \Sigma^* (\Delta(p, x) \in F \Leftrightarrow \Delta(q, x) \in F)$, we say p and q are equivalent (or indistinguishable).
- **Example[13.2]: (next slide)**
 - state 3 and 4 are equivalent.
 - States 1 and 2 are equivalent.
- **Equivalent states can be merged to form a simpler machine.**

Example 13.2:

Example 13.2: Witness for states that are distinguishable

1. States b/t $\{0,3,4\}$ and $\{1,2,5\}$ can be distinguished by the empty string ϵ .
2. States b/t $\{1,2\}$ and $\{5\}$ can be distinguished by a or b.
3. States b/t $\{0\}$ and $\{3,4\}$ can be distinguished by aa,ab, ba or bb.
4. There is no way to distinguish b/t 1 and 2, and b/t 3 and 4.

Quotient Construction

- $M=(Q, \Sigma, \delta, s, F)$: a DFA.
- \approx : a relation on Q defined by:
 - $p \approx q \iff \forall x \in \Sigma^* \quad \Delta(p,x) \in F \iff \Delta(q,x) \in F$
- Property: \approx is an equivalence (i.e., reflexive, symmetric and transitive) relation.
- Hence it partitions Q into equivalence classes :
 - $[p] =_{\text{def}} \{q \in Q \mid p \approx q\}$ for $p \in Q$.
 - $Q/\approx =_{\text{def}} \{[p] \mid p \in Q\}$ is the quotient set.
 - Every $p \in Q$ belongs to exactly one class (which is $[p]$)
 - $p \approx q \iff [p]=[q]$ //why? since $p \approx q$ implies ($p \approx r \iff q \approx r$).
- Ex: From Ex 13.2, we have $0, 1 \approx 2, 3 \approx 4, 5$.
 - $\Rightarrow [0] = \{0\}, [1] = \{1,2\}, [2]=\{1,2\}, [3]=\{3,4\}, [4]=\{3,4\}$ and
 - $[5] = \{5\}$. As a result, $[1] = [2] = \{1,2\}, [3]=[4]= \{3,4\}$ and
 - $Q/\approx = \{ \{0\}, \{1,2\}, \{3,4\}, \{5\} \} = \{ [0], [1], [2], [3], [4], [5] \} = \{ [0], [1], [3], [5] \}$.

the function δ' is well-defined.

- Define a DFA called the quotient machine $M/\approx = \langle Q', \Sigma, \delta', s', F' \rangle$ where

□ $Q' = Q/\approx$; $s' = [s]$; $F' = \{[p] \mid p \in F\}$; and

□ $\delta'([p], a) = [\delta(p, a)]$ for all $p \in Q$ and $a \in \Sigma$. But well-defined?

Lem 13.5. if $p \approx q$ then $\delta(p, a) \approx \delta(q, a)$.

Hence $[p] = [q] \Rightarrow p \approx q \Rightarrow \delta(p, a) \approx \delta(q, a) \Rightarrow [\delta(p, a)] = [\delta(q, a)]$

Pf: By def. $[\delta(p, a)] = [\delta(q, a)]$ iff $\delta(p, a) \approx \delta(q, a)$

iff $\forall y \in \Sigma^* \Delta(\delta(p, a), y) \in F \Leftrightarrow \Delta(\delta(q, a), y) \in F$

iff $\forall y \in \Sigma^* \Delta(p, ay) \in F \Leftrightarrow \Delta(q, ay) \in F$

if $p \approx q$.

Lemma 13.6. $p \in F$ iff $[p] \in F'$.

pf: \Rightarrow : trivial.

\Leftarrow : need to show that if $q \approx p$ and $p \in F$, then $q \in F$.

But this is trivial since $p = \Delta(p, \varepsilon) \in F$ iff $\Delta(q, \varepsilon) = q \in F$

Properties of the quotient machine.

Lemma 13.7: $\forall x \in \Sigma^*, \Delta'([p], x) = [\Delta(p, x)].$

Pf: By induction on $|x|$.

Basis $x = \varepsilon$: $\Delta'([p], \varepsilon) = [p] = [\Delta(p, \varepsilon)].$

Ind. step: Assume $\Delta'([p], x) = [\Delta(p, x)]$ and let $a \in \Sigma$.

$\Delta'([p], xa) = \delta'(\Delta'([p], x), a) = \delta'([\Delta(p, x)], a) \text{ --- ind. hyp.}$

$= [\delta(\Delta(p, x), a)] \text{ -- def. of } \delta'$

$= [\Delta(p, xa)]. \text{ -- def. of } \Delta.$

Theorem 13.8: $L(M/\approx) = L(M).$

Pf: $\forall x \in \Sigma^*,$

$x \in L(M/\approx) \text{ iff } \Delta'(s', x) \in F'$

$\text{iff } \Delta'([s], x) \in F' \text{ iff } [\Delta(s, x)] \in F' \text{ --- lem 13.7}$

$\text{iff } \Delta(s, x) \in F \text{ --- lem 13.6}$

$\text{iff } x \in L(M).$

M/\approx need not be merged further

- **Theorem:** $((M/\approx) / \approx) = M/\approx$

Pf: Denote the second \approx by \sim . I.e.

$$[p] \sim [q] \text{ iff } \forall x \in \Sigma^*, \Delta'([p], x) \in F' \Leftrightarrow \Delta'([q], x) \in F'$$

Now

$$[p] \sim [q]$$

$$\text{iff } \forall x \in \Sigma^*, \Delta'([p], x) \in F' \Leftrightarrow \Delta'([q], x) \in F' \text{ -- def. of } \sim$$

$$\text{iff } \forall x \in \Sigma^*, [\Delta(p, x)] \in F' \Leftrightarrow [\Delta(q, x)] \in F' \text{ -- lem 13.7}$$

$$\text{iff } \forall x \in \Sigma^*, \Delta(p, x) \in F \Leftrightarrow \Delta(q, x) \in F \text{ -- lem 13.6}$$

$$\text{iff } p \approx q \text{ -- def of } \approx$$

$$\text{iff } [p] = [q] \text{ -- property of equivalence } \approx$$

A minimization algorithm

1. Write down a table of all pairs $\{p,q\}$, initially unmarked.
2. mark $\{p,q\}$ if $p \in F$ and $q \notin F$ or vice versa.
3. Repeat until no additional pairs marked:
 - 3.1 if \exists unmarked pair $\{p,q\}$ s.t. $\{\delta(p,a), \delta(q,a)\}$ is marked for some $a \in \Sigma$, then mark $\{p,q\}$.
4. When done, $p \approx q$ iff $\{p,q\}$ is not marked.

Let M_k ($k \geq 0$) be the set of pairs marked after the k -th iteration of step 3. [M_0 is the set of pairs before step 3.]

Notes: (1) $M = \bigcup_{k \geq 0} M_k$ is the final set of pairs marked by the alg. (2) The algorithm must terminate since there are totally only $C(n,2)$ pairs and each iteration of step 3 must mark at least one pair for it to not terminate..

An Example:

● The DFA: (Ex 13.2)

	a	b
>0	1	2
1F	3	4
2F	4	3
3	5	5
4	5	5
5F	5	5

Initial Table

1	-				
2	-	-			
3	-	-	-		
4	-	-	-	-	
5	-	-	-	-	-
	0	1	2	3	4

After step 2 (M_0)

1	M				
2	M	-			
3	-	M	M		
4	-	M	M	-	
5	M	-	-	M	M
	0	1	2	3	4

After first pass of step 3 (M_1)

1	M				
2	M	-			
3	-	M	M		
4	-	M	M	-	
5	M	M	M	M	M
	0	1	2	3	4

2nd pass of step 3. (M_2 & M_3)

- The result : $1 \approx 2$ and $3 \approx 4$.

1	M				
2	M	-			
3	M2	M	M		
4	M2	M	M	-	
5	M	M1	M1	M	M
	0	1	2	3	4

Correctness of the minimization algorithm

Let M_k ($k \geq 0$) be the set of pairs marked after the k -th iteration of step 3. [and M_0 is the set of pairs before step 3.]

Lemma: $\{p,q\} \in M_k$ iff $\exists x \in \Sigma^*$ of length $\leq k$ s.t. $\Delta(p,x) \in F$ and $\Delta(q,x) \notin F$ or vice versa,

Pf: By ind. on k . **Basis** $k = 0$. trivial.

Ind. step: $\exists x \in \Sigma^*$ of length $\leq k+1$ s.t. $\Delta(p,x) \in F \Leftrightarrow \Delta(q,x) \notin F$,

iff $\exists y \in \Sigma^*$ of length $\leq k$ s.t. $\Delta(p,y) \in F \Leftrightarrow \Delta(q,y) \notin F$, or

$\exists ay \in \Sigma^*$ of length $\leq k+1$ s.t. $\Delta(\delta(p,a),y) \in F \Leftrightarrow \Delta(\delta(q,a),y) \notin F$,

iff $\{p, q\} \in M_k$ or $\{\delta(p,a), \delta(q,a)\} \in M_k$ for some $a \in \Sigma$.

iff $\{p,q\} \in M_{k+1}$.

Theorem 14.3: The pair $\{p,q\}$ is marked by the algorithm iff $\text{not}(p \approx q)$
(i.e., $\exists x \in \Sigma^*$ s.t. $\Delta(p,x) \in F \Leftrightarrow \Delta(q,x) \notin F$)

Pf: $\text{not}(p \approx q)$ iff $\exists x \in \Sigma^*$ s.t. $\Delta(p,x) \in F \Leftrightarrow \Delta(q,x) \notin F$

iff $\{p,q\} \in M_k$ for some $k \geq 0$

iff $\{p,q\} \in M = \bigcup_{k \geq 0} M_k$.
