

## Check polynomials and parity check matrices for cyclic codes

Let  $C$  be a cyclic  $[n, k]$ -code with the generator polynomial  $g(x)$  (of degree  $n - k$ ). By the last theorem  $g(x)$  is a factor of  $x^n - 1$ . Hence

$$x^n - 1 = g(x)h(x)$$

for some  $h(x)$  of degree  $k$  (where  $h(x)$  is called the check polynomial of  $C$ ).

**Theorem** Let  $C$  be a cyclic code in  $R_n$  with a generator polynomial  $g(x)$  and a check polynomial  $h(x)$ . Then an  $c(x) \in R_n$  is a codeword of  $C$  if  $c(x)h(x) \equiv 0$  - this and next congruences are modulo  $x^n - 1$ .

**Proof** Note, that  $g(x)h(x) = x^n - 1 \equiv 0$

$$\begin{aligned} \text{(i)} \quad c(x) \in C &\Rightarrow c(x) = a(x)g(x) \text{ for some } a(x) \in R_n \\ &\Rightarrow c(x)h(x) = a(x) \underbrace{g(x)h(x)}_{\equiv 0} \equiv 0. \end{aligned}$$

$$\text{(ii)} \quad c(x)h(x) \equiv 0$$

$$c(x) = q(x)g(x) + r(x), \deg r(x) < n - k = \deg g(x)$$

$$c(x)h(x) \equiv 0 \Rightarrow r(x)h(x) \equiv 0 \pmod{x^n - 1}$$

Since  $\deg(r(x)h(x)) < n - k + k = n$ , we have  $r(x)h(x) = 0$  in  $F[x]$  and therefore

$$r(x) = 0 \Rightarrow c(x) = q(x)g(x) \in C.$$

# POLYNOMIAL REPRESENTATION of DUAL CODES

Since  $\dim(\langle h(x) \rangle) = n - k = \dim(C^\perp)$  we might easily be fooled to think that the check polynomial  $h(x)$  of the code  $C$  generates the dual code  $C^\perp$ .

Reality is “slightly different”:

**Theorem** Suppose  $C$  is a cyclic  $[n,k]$ -code with the check polynomial

$$h(x) = h_0 + h_1x + \dots + h_kx^k,$$

then

(i) a parity-check matrix for  $C$  is

$$H = \begin{pmatrix} h_k & h_{k-1} & \dots & h_0 & 0 & \dots & 0 \\ 0 & h_k & \dots & h_1 & h_0 & \dots & 0 \\ \dots & \dots & & & & & \\ 0 & 0 & \dots & 0 & h_k & \dots & h_0 \end{pmatrix}$$

(ii)  $C^\perp$  is the cyclic code generated by the polynomial

$$\bar{h}(x) = h_k + h_{k-1}x + \dots + h_0x^k$$

i.e. the reciprocal polynomial of  $h(x)$ .

# POLYNOMIAL REPRESENTATION of DUAL CODES

**Proof** A polynomial  $c(x) = c_0 + c_1x + \dots + c_{n-1}x^{n-1}$  represents a code from  $C$  if  $c(x)h(x) = 0$ . For  $c(x)h(x)$  to be 0 the coefficients at  $x^k, \dots, x^{n-1}$  must be zero, i.e.

$$c_0h_k + c_1h_{k-1} + \dots + c_kh_0 = 0$$

$$c_1h_k + c_2h_{k-1} + \dots + c_{k+1}h_0 = 0$$

$$\dots \dots$$

$$c_{n-k-1}h_k + c_{n-k}h_{k-1} + \dots + c_{n-1}h_0 = 0$$

Therefore, any codeword  $c_0 c_1 \dots c_{n-1} \in C$  is orthogonal to the word  $h_k h_{k-1} \dots h_0 00 \dots 0$  and to its cyclic shifts.

Rows of the matrix  $H$  are therefore in  $C^\perp$ . Moreover, since  $h_k = 1$ , these row-vectors are linearly independent. Their number is  $n - k = \dim(C^\perp)$ . Hence  $H$  is a generator matrix for  $C^\perp$ , i.e. a parity-check matrix for  $C$ .

In order to show that  $C^\perp$  is a cyclic code generated by the polynomial

$$\bar{h}(x) = h_k + h_{k-1}x + \dots + h_0x^k$$

it is sufficient to show that  $\bar{h}(x)$  is a factor of  $x^n - 1$ .

Observe that  $\bar{h}(x) = x^k h(x^{-1})$  and since  $h(x^{-1})g(x^{-1}) = (x^{-1})^n - 1$

we have that  $x^k h(x^{-1})x^{n-k}g(x^{-1}) = x^n(x^{-n} - 1) = 1 - x^n$

and therefore  $\bar{h}(x)$  is indeed a factor of  $x^n - 1$ .

# ENCODING with CYCLIC CODES I

Encoding using a cyclic code can be done by a multiplication of two polynomials - a message polynomial and the generating polynomial for the cyclic code.

Let  $C$  be an  $(n,k)$ -code over an field  $F$  with the generator polynomial  $g(x) = g_0 + g_1 x + \dots + g_{r-1} x^{r-1}$  of degree  $r = n - k$ .

If a message vector  $m$  is represented by a polynomial  $m(x)$  of degree  $k$  and  $m$  is encoded by

$$m \Rightarrow c = mG_1,$$

then the following relation between  $m(x)$  and  $c(x)$  holds

$$c(x) = m(x)g(x).$$

Such an encoding can be realized by the shift register shown in Figure below, where input is the  $k$ -bit message to be encoded followed by  $n - k$  0's and the output will be the encoded message

Shift-register encodings of cyclic codes. Small circles represent multiplication by the corresponding constant,  $\oplus$  nodes represent modular addition, squares are delay elements

## ENCODING of CYCLIC CODES II

Another method for encoding of cyclic codes is based on the following (so called systematic) representation of the generator and parity-check matrices for cyclic codes.

**Theorem** Let  $C$  be an  $(n,k)$ -code with generator polynomial  $g(x)$  and  $r = n - k$ . For  $i = 0, 1, \dots, k - 1$ , let  $G_{2,i}$  be the length  $n$  vector whose polynomial is  $G_{2,i}(x) = x^{r+i} - x^{r+i} \bmod g(x)$ . Then the  $k \times n$  matrix  $G_2$  with row vectors  $G_{2,i}$  is a generator matrix for  $C$ .

Moreover, if  $H_{2,j}$  is the length  $n$  vector corresponding to polynomial  $H_{2,j}(x) = x^j \bmod g(x)$ , then the  $r \times n$  matrix  $H_2$  with row vectors  $H_{2,j}$  is a parity check matrix for  $C$ . If the message vector  $m$  is encoded by

$$m \Rightarrow c = mG_2,$$

then the relation between corresponding polynomials is

$$c(x) = x^r m(x) - [x^r m(x)] \bmod g(x).$$

On this basis one can construct the following shift-register encoder for the case of a systematic representation of the generator for a cyclic code:

Shift-register encoder for systematic representation of cyclic codes. Switch A is closed for first  $k$  ticks and closed for last  $r$  ticks; switch B is down for first  $k$  ticks and up for last  $r$  ticks.

## Hamming codes as cyclic codes

**Definition** (Again!) Let  $r$  be a positive integer and let  $H$  be an  $r \times (2^r - 1)$  matrix whose columns are distinct non-zero vectors of  $V(r, 2)$ . Then the code having  $H$  as its parity-check matrix is called binary **Hamming code** denoted by  $Ham(r, 2)$ .

It can be shown that binary Hamming codes are equivalent to cyclic codes.

**Theorem** The binary Hamming code  $Ham(r, 2)$  is equivalent to a cyclic code.

**Definition** If  $p(x)$  is an irreducible polynomial of degree  $r$  such that  $x$  is a primitive element of the field  $F[x] / p(x)$ , then  $p(x)$  is called a primitive polynomial.

**Theorem** If  $p(x)$  is a primitive polynomial over  $GF(2)$  of degree  $r$ , then the cyclic code  $\langle p(x) \rangle$  is the code  $Ham(r, 2)$ .

## Hamming codes as cyclic codes

**Example** Polynomial  $x^3 + x + 1$  is irreducible over  $GF(2)$  and  $x$  is primitive element of the field  $F_2[x] / (x^3 + x + 1)$ .

$$F_2[x] / (x^3 + x + 1) = \\ \{0, x, x^2, x^3 = x + 1, x^4 = x^2 + x, x^5 = x^2 + x + 1, x^6 = x^2 + 1\}$$

The parity-check matrix for a cyclic version of  $Ham(3,2)$

$$H = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 & 1 \end{pmatrix}$$

# PROOF of THEOREM

The binary Hamming code  $Ham(r, 2)$  is equivalent to a cyclic code.

It is known from algebra that if  $p(x)$  is an irreducible polynomial of degree  $r$ , then the ring  $F_2[x] / p(x)$  is a field of order  $2^r$ .

In addition, every finite field has a primitive element. Therefore, there exists an element  $\alpha$  of  $F_2[x] / p(x)$  such that

$$F_2[x] / p(x) = \{0, 1, \alpha, \alpha^2, \dots, \alpha^{2^r-2}\}.$$

Let us identify an element  $a_0 + a_1 \alpha + \dots + a_{r-1} \alpha^{r-1}$  of  $F_2[x] / p(x)$  with the column vector

$$(a_0, a_1, \dots, a_{r-1})^T$$

and consider the binary  $r \times (2^r - 1)$  matrix

$$H = [1 \quad \alpha \quad \alpha^2 \quad \dots \quad \alpha^{2^r-2}].$$

Let now  $C$  be the binary linear code having  $H$  as a parity check matrix.

Since the columns of  $H$  are all distinct non-zero vectors of  $V(r, 2)$ ,  $C = Ham(r, 2)$ .

Putting  $n = 2^r - 1$  we get

$$C = \{f_0 f_1 \dots f_{n-1} \in V(n, 2) \mid f_0 + f_1 \alpha + \dots + f_{n-1} \alpha^{n-1} = 0\} \quad (2)$$

$$= \{f(x) \in R_n \mid f(\alpha) = 0 \text{ in } F_2[x] / p(x)\} \quad (3)$$

If  $f(x) \in C$  and  $r(x) \in R_n$ , then  $r(x)f(x) \in C$  because

$$r(\alpha)f(\alpha) = r(\alpha) \bullet 0 = 0$$

and therefore, by one of the previous theorems, this version of  $Ham(r, 2)$  is cyclic.

# BCH codes and Reed-Solomon codes

To the most important cyclic codes for applications belong **BCH codes** and **Reed-Solomon codes**.

**Definition** A polynomial  $p$  is said to be minimal for a complex number  $x$  in  $Z_q$  if  $p(x) = 0$  and  $p$  is irreducible over  $Z_q$ .

**Definition** A cyclic code of codewords of length  $n$  over  $Z_q$ ,  $q = p^r$ ,  $p$  is a prime, is called **BCH code**<sup>1</sup> of distance  $d$  if its generator  $g(x)$  is the least common multiple of the minimal polynomials for

$$\omega^l, \omega^{l+1}, \dots, \omega^{l+d-2}$$

for some  $l$ , where

$\omega$  is the primitive  $n$ -th root of unity.

If  $n = q^m - 1$  for some  $m$ , then the BCH code is called **primitive**.

**Definition** A **Reed-Solomon** code is a primitive BCH code with  $n = q - 1$ .

**Properties:**

- Reed-Solomon codes are self-dual.

<sup>1</sup>BCH stands for Bose and Ray-Chaudhuri and Hocquenghem who discovered these codes.

# CONVOLUTION CODES

Very often it is important to encode an infinite stream or several streams of data  
– say bits.

**Convolution codes, with simple encoding and decoding, are quite a simple generalization of linear codes and have encodings as cyclic codes.**

*An  $(n,k)$  convolution code (CC) is defined by an  $k \times n$  generator matrix, entries of which are polynomials over  $F_2$*

For example,

$$G_1 = [x^2 + 1, x^2 + x + 1]$$

is the generator matrix for a (2,1) convolution code  $CC_1$  and

$$G_2 = \begin{pmatrix} 1+x & 0 & x+1 \\ 0 & 1 & x \end{pmatrix}$$

is the generator matrix for a (3,2) convolution code  $CC_2$

# ENCODING of FINITE POLYNOMIALS

An  $(n,k)$  convolution code with a  $k \times n$  generator matrix  $G$  can be used to encode a  $k$ -tuple of plain-polynomials (polynomial input information)

$$I=(I_0(x), I_1(x), \dots, I_{k-1}(x))$$

to get an  $n$ -tuple of crypto-polynomials

$$C=(C_0(x), C_1(x), \dots, C_{n-1}(x))$$

As follows

$$C = I \cdot G$$

## EXAMPLES

### EXAMPLE 1

$$\begin{aligned}(x^3 + x + 1).G_1 &= (x^3 + x + 1) \cdot (x^2 + 1, x^2 + x + 1) \\ &= (x^5 + x^2 + x + 1, x^5 + x^4 + 1)\end{aligned}$$

### EXAMPLE 2

$$(x^2 + x, x^3 + 1).G_2 = (x^2 + x, x^3 + 1) \cdot \begin{pmatrix} 1 & 0 & x + 1 \\ 0 & 1 & x \end{pmatrix}$$

# ENCODING of INFINITE INPUT STREAMS

**The way infinite streams are encoded using convolution codes will be illustrated on the code  $CC_1$ .**

An input stream  $I = (I_0, I_1, I_2, \dots)$  is mapped into the output stream  $C = (C_{00}, C_{10}, C_{01}, C_{11}, \dots)$  defined by

$$C_0(x) = C_{00} + C_{01}x + \dots = (x^2 + 1) I(x)$$

and

$$C_1(x) = C_{10} + C_{11}x + \dots = (x^2 + x + 1) I(x).$$

The first multiplication can be done by the first shift register from the next figure; second multiplication can be performed by the second shift register on the next slide and it holds

$$C_{0i} = I_i + I_{i+2}, \quad C_{1i} = I_i + I_{i-1} + I_{i-2}.$$

***That is the output streams  $C_0$  and  $C_1$  are obtained by convolving the input stream with polynomials of  $G_1$ ,***

# ENCODING

## The first shift register

will multiply the input stream by  $x^2+1$  and the second shift register

will multiply the input stream by  $x^2+x+1$ .

# ENCODING and DECODING

The following shift-register will therefore be an encoder for the code  $CC_1$

For encoding of convolution codes so called

**Viterbi algorithm**

Is used.
