

RECURSION

Recursion

- A **recursive definition** is when something is defined *partly* in terms of itself
- Here's the mathematical definition of **factorial**:

$$\text{factorial}(n) = \begin{cases} 1, & \text{if } n \leq 1 \\ n * \text{factorial}(n - 1) & \text{otherwise} \end{cases}$$

- Here's the programming definition of factorial:

```
static int factorial(int n) {  
    if (n <= 1) return 1;  
    else return n * factorial(n - 1);  
}
```

Supporting recursion

```
static int factorial(int n) {  
    if (n <= 1) return 1;  
    else return n * factorial(n - 1);  
}
```

- If you call $x = \text{factorial}(3)$, this enters the factorial method with $n=3$ on the stack
- | factorial calls itself, putting $n=2$ on the stack
- | | factorial calls itself, putting $n=1$ on the stack
- | | factorial returns 1
- | factorial has $n=2$, computes and returns $2*1 = 2$
- factorial has $n=3$, computes and returns $3*2 = 6$

Factorial

- `x = factorial(3)`

3 is put on stack as `n`

- ```
static int factorial(int n) {
 //n=3
 int r = 1; r is put on stack with value 1
 if (n <= 1) return r;
 else {
 r = n * factorial(n - 1);
 return r;
 }
}
```

All references to `r` use this `r`

All references to `n` use this `n`

Now we recur with `2...`

`r=1`

`n=3`

# Factorial

- `r = n * factorial(n - 1);`

2 is put on stack as n

- `static int factorial(int n) { // n=2`

`int r = 1;`

r is put on stack with value 1

`if (n <= 1) return r;`

`else {`

`r = n * factorial(n - 1);`

Now using this r

`return r;`

And this n

`}`

`}`

Now we recur with 1...

r=1

n=2

r=1

n=3

# Factorial

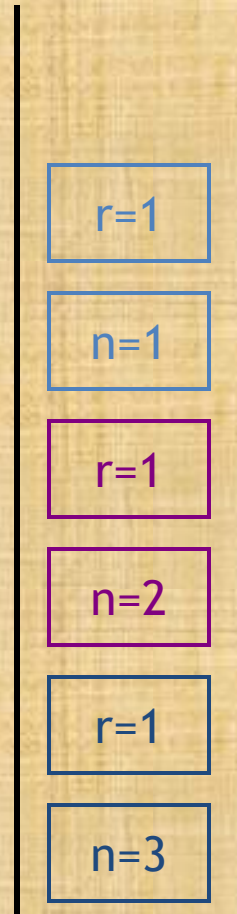

- $r = n * \text{factorial}(n - 1);$

1 is put on stack as n

- ```
static int factorial(int n) {  
    int r = 1;  
    if (n <= 1) return r;  
    else {  
        r = n * factorial(n - 1);  
        return r;  
    }  
}
```

Now using this r

r is put on stack with value 1 And this n

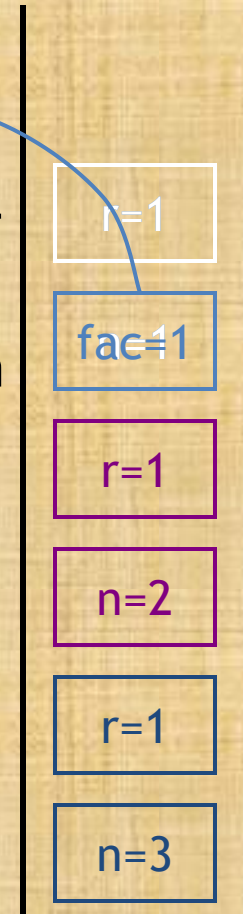

Now we pop r and n off the stack and return 1 as factorial(1)

Factorial

- $r = n * \text{factorial}(n - 1);$

- ```
static int factorial(int n) {
 int r = 1;
 if (n <= 1) return r;
 else {
 r = n * factorial(n - 1);
 return r;
 }
}
```

Now using this r  
And  
this n

Now we pop r and n off the  
stack and return 1 as  
factorial(1)

# Factorial

- $r = n * \text{factorial}(n - 1);$

- ```
static int factorial(int n) {  
    int r = 1;  
    if (n <= 1) return r;  
    else {  
        r = n * factorial(n - 1);  
        return r;  
    }  
}
```

Now using this r

And
this n

$2 * 1$ is 2;
Pop r and n;

Return 2

fac=2

r=1

n=3

Factorial

- x = factorial(3)

- static int factorial(int n) {
 int r = 1;
 if (n <= 1) return r;
 else {
 r = n * factorial(n - 1);
 }
 return r;
}

3 * 2 is 6;
Pop r and n;

Return 6

Now using this r

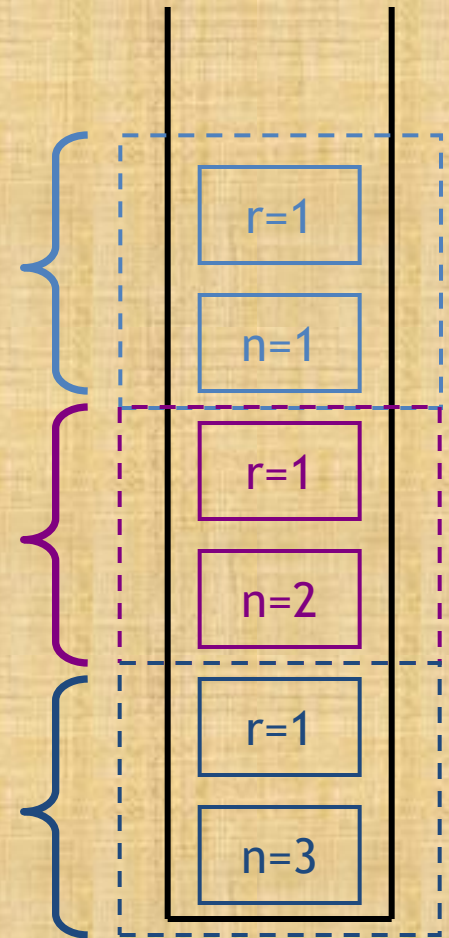

And
this n

r=1

fac=6

Stack frames

- Rather than pop variables off the stack one at a time, they are usually organized into **stack frames**
- Each frame provides a set of variables and their values
- This allows variables to be popped off all at once
- There are several different ways stack frames can be implemented

Summary

- Stacks are useful for working with any nested structure, such as:
 - Arithmetic expressions
 - Nested statements in a programming language
 - Any sort of nested data
