TYPE CONVERSION

Basic Data Types

Integral Types

Integers are stored in various sizes. They can be signed or unsigned.

Example

Suppose an integer is represented by a byte (8 bits). Leftmost bit is sign bit. If the sign bit is 0, the number is treated as positive.

Bit pattern 01001011 = 75 (decimal).

The largest positive number is $011111111 = 2^7 - 1 = 127$.

Negative numbers are stored as two's complement or as one's complement.

- -75 = 10110100 (one's complement).
- -75 = 10110101 (two's complement).

Basic Data Types

Integral Types

char

Stored as 8 bits. Unsigned 0 to 255.

Signed -128 to 127.

short int

Stored as 16 bits. Unsigned 0 to 65535.

Signed -32768 to 32767.

• int

Same as either short or long int.

long int 4294967295. Stored as 32 bits. Unsigned 0 to

Signed -2147483648 to 2147483647

Basic Data Types

- Floating Point Numbers
 - Floating point numbers are rational numbers. Always signed numbers.
 - float Approximate precision of 6 decimal digits.
 - Typically stored in 4 bytes with 24 bits of signed mantissa and 8 bits of signed exponent.
 - double Approximate precision of 14 decimal digits.
 - Typically stored in 8 bytes with 56 bits of signed mantissa and 8 bits of signed exponent.
 - One should check the file limits.h to what is implemented on a particular machine.

Constants

- Numerical Constants
 - Constants like 12, 253 are stored as int type. No decimal point.
 - 12L or 12l are stored as long int.
 - 12U or 12u are stored as unsigned int.
 - 12UL or 12ul are stored as unsigned long int.
 - Numbers with a decimal point (12.34) are stored as double.
 - Numbers with exponent $(12e-3 = 12 \times 10^{-3})$ are stored as double.
 - 12.34f or 1.234e1f are stored as float.
 - These are not valid constants:

```
25,000
```

7.1e 4 \$200 2.3e-3.4 etc.

Constants

- Character and string constants
 - `c', a single character in single quotes are stored as char.
 Some special character are represented as two characters in single quotes.

```
'\n' = newline, '\t' = tab, '\\' = backlash, '\"' = double quotes.

Char constants also can be written in terms of their ASCII code.

'\060' = '0' (Decimal code is 48).
```

 A sequence of characters enclosed in double quotes is called a string constant or string literal. For example

```
"Charu"
"A"
"3/9"
"x = 5"
```

Variables

- Naming a Variable
 - Must be a valid identifier.
 - Must not be a keyword
 - Names are case sensitive.
 - Variables are identified by only first 32 characters.
 - Library commonly uses names beginning with _.
 - Naming Styles: Uppercase style and Underscore style
 - lowerLimit lower limit
 - incomeTax income_tax

Declarations

- Declaring a Variable
 - Each variable used must be declared.
 - A form of a declaration statement is data-type var1, var2,...;
 - Declaration announces the data type of a variable and allocates appropriate memory location. No initial value (like 0 for integers) should be assumed.
 - It is possible to assign an initial value to a variable in the declaration itself.

```
data-type var = expression;
• Examples
int sum = 0;
char newLine = '\n';
float epsilon = 1.0e-6;
```

Global and Local Variables

Global Variables

- These variables are declared outside all functions.
- Life time of a global variable is the entire execution period of the program.
- Can be accessed by any function defined below the declaration, in a file.

```
/* Compute Area and Perimeter of a
  circle */
#include <stdio.h>
float pi = 3.14159; /* Global */
main() {
  float rad; /* Local */
 printf( "Enter the radius " );
  scanf("%f" , &rad);
  if ( rad > 0.0 ) {
   float area = pi * rad * rad;
   float peri = 2 * pi * rad;
   printf( "Area = %f\n" , area );
   printf( "Peri = %f\n" , peri );
  else
   printf( "Negative radius\n");
 printf( "Area = %f\n" , area );
```

Global and Local Variables

Local Variables

- These variables are declared inside some functions.
- Life time of a local variable is the entire execution period of the function in which it is defined.
- Cannot be accessed by any other function.
- In general variables declared inside a block are accessible only in that block.

```
/* Compute Area and Perimeter of a
  circle */
#include <stdio.h>
float pi = 3.14159; /* Global */
main() {
  float rad; /* Local */
 printf( "Enter the radius " );
  scanf("%f" , &rad);
  if ( rad > 0.0 ) {
   float area = pi * rad * rad;
   float peri = 2 * pi * rad;
   printf( "Area = %f\n" , area );
   printf( "Peri = %f\n" , peri );
  else
   printf( "Negative radius\n");
 printf( "Area = %f\n" , area );
```

OperatorsArithmetic Operators

- - +, , *, / and the modulus operator %.
 - + and have the same precedence and associate left to right.

$$3 - 5 + 7 = (3 - 5) + 7 \neq 3 - (5 + 7)$$

 $3 + 7 - 5 + 2 = ((3 + 7) - 5) + 2$

- *, /, % have the same precedence and associate left to right.
- The +, group has lower precendence than the *, / % group.

```
3 - 5 * 7 / 8 + 6 / 2
3 - 35 / 8 + 6 / 2
3 - 4.375 + 6 / 2
3 - 4.375 + 3
-1.375 + 3
1.625
```

- Arithmetic Operators
 - % is a modulus operator. x % y results in the remainder when x is divided by y and is zero when x is divisible by y.
 - Cannot be applied to float or double variables.
 - Example

```
if ( num % 2 == 0 )
printf("%d is an even number\n", num)';
else
printf("%d is an odd number\n", num);
```

Type Conversions

- The operands of a binary operator must have a the same type and the result is also of the same type.
- Integer division:

$$c = (9 / 5)*(f - 32)$$

The operands of the division are both int and hence the result also would be int. For correct results, one may write

$$c = (9.0 / 5.0)*(f - 32)$$

 In case the two operands of a binary operator are different, but compatible, then they are converted to the same type by the compiler.
 The mechanism (set of rules) is called Automatic Type Casting.

$$c = (9.0 / 5)*(f - 32)$$

 It is possible to force a conversion of an operand. This is called Explicit Type casting.

$$c = ((float) 9 / 5)*(f - 32)$$

Automatic Type Casting

- 1. char and short operands are converted to int
- 2. Lower data types are converted to the higher data types and result is of higher type.
- 3. The conversions between unsigned and signed types may not yield intuitive results.
- 4. Example

```
float f; double d; long l;
int i; short s;
d + f f will be converted to double
i / s s will be converted to int
l / i i is converted to long; long result
```

Hierarchy

Double

float

long

Int

Short and

char

Explicit Type Casting

- The general form of a type casting operator is
- (type-name) expression
- It is generally a good practice to use explicit casts than to rely on automatic type conversions.
- Example

```
C = (float)9 / 5 * (f - 32)
```

- float to int conversion causes truncation of fractional part
- double to float conversion causes rounding of digits
- long int to int causes dropping of the higher order bits.

Precedence and Order of

+ Unary plus Unary minus Unary plus Unary minus Unary mi	Left to right Right to left	cludes 2 is ve
+ Unary plus Unary minus Unary plus Unary minus Unary mi	Right to left Tallogmi vi	cludes s is ve
++ Increment Decrement ! Logical negation		
* Pointer reference (indirection) & Address sizeof (type) Type cast (conversion)	edence rules say that th (&&) and the relational cuted first. This is equiva	
* Multiplication / Division % Modulus	Left to right	3

Precedence and Order of

OPERATOR	DESCRIPTION	ASSOCIATIVITY
<< >>>	Left shift Right shift	Left to right
< <= >> >=	Less than Less than or equal to Greater than Greater than or equal to	Left to right
== !=	Equality Inequality	Left to right
&	Bitwise AND	Left to right
•	Bitwise XOR	Left to right
1	Bitwise OR siduob s m	Left to right
&&	Logical AND	Left to right
#	Logical OR	Left to right
?:	Conditional expression	Right to left
= *= /= %=	Assignment operators	Right to left
+= -= &= ^= = <<= >>=	salary 00 ches : 1500.00 y computer sold : 200.00 the of althoughly sales sold percent	
gi asvig givenig	Comma operator	Left to right

- Relational Operators
 - <, <=, >>=, ==, != are the relational operators. The expression operand1 relational-operator operand2 takes a value of 1(int) if the relationship is true and 0(int) if relationship is false.
 - Example

```
int a = 25, b = 30, c, d;
c = a < b;
d = a > b;
```

value of c will be 1 and that of d will be 0.

Logical Operators

- &&, | | and ! are the three logical operators.
- expr1 && expr2 has a value 1 if expr1 and expr2 both are nonzero.
- expr1 | expr2 has a value 1 if expr1 and expr2 both are nonzero.
- !expr1 has a value 1 if expr1 is zero else 0.
- Example
- if (marks >= 40 && attendance >= 75) grade = 'P'
- If (marks < 40 | attendance < 75) grade = 'N'

- Assignment operators
 - The general form of an assignment operator is
 - v op= exp
 - Where v is a variable and op is a binary arithmetic operator. This statement is equivalent to
 - $v = v \circ p (exp)$

•	a	=	a	+	b	can be written as	а	+=	b
•	a	=	a	*	b	can be written as	a	*=	b
•	a	=	a	/	b	can be written as	a	/=	b
•	а	=	а	_	b	can be written as	а	-=	b

- Increment and Decrement Operators
 - The operators ++ and -- are called increment and decrement operators.
 - a++ and ++a are equivalent to a += 1.
 - a-- and --a are equivalent to a -= 1.
 - ++a op b is equivalent to a ++; a op b;
 - a++ op b is equivalent to a op b; a++;
 - Example

Let
$$b = 10$$
 then
 $(++b)+b+b = 33$
 $b+(++b)+b = 33$
 $b+b+(++b) = 31$
 $b+b*(++b) = 132$

Floating Point Arithmetic

- Representation
 - All floating point numbers are stored as
 - such that d₁ is nonzero. B is the base. p is the precision or number of significant digits. e is the exponent. All these put together have finite number of bits (usually 32 or 64 bits) of storage.
 - Example
 - Assume B = 10 and p = 3.
 - 23.7 = +0.237E2
 - 23.74 = +0.237E2
 - 37000 = +0.370E5
 - 37028 = +0.370E5
 - -0.000124 = -0.124E-4

Floating Point Arithmetic

Representation

- $S_k = \{ x \mid B^{k-1} \le x < B^k \}$. Number of elements in each Sk is same. In the previous example it is 900.
- Gap between seuccessive numbers of Sk is B^{k-p}.
- B1-p is called machine epsilon. It is the gap between 1 and next representable number.
- Underflow and Overflow occur when number cannot be represented because it is too small or too big.
- Two floating points are added by aligning decimal points.
- Floating point arithmetic is not associative and distributive.
